

## SPECIFICATION

### TITLE OF THE INVENTION

Information Recording Medium, Apparatus and Method for  
Performing After-recording on the Recording Medium

5

### BACKGROUND OF THE INVENTION

#### <1.Field of The Invention>

The present invention relates to an information recording medium  
like an optical disc which has large capacity and to/from which data are written/  
10 read in high speed, and more particularly to a recording medium which can  
perform after-recording, an apparatus and a method for recording thereto.

#### <2.Related Art>

In the field of a writable optical disc having an upper bound of  
15 approximately 650 MB, a phase change type disc DVD-RAM having a capacity  
of several GB has appeared. Moreover, in addition to the practical use of  
MPEG (MPEG2) which is the coding standard of digital AV data, the DVD-RAM  
has been expected as recording and reproducing media in the AV field as well  
as computer application. In other words, it is expected that the DVD-RAM will  
20 spread as media in place of a magnetic tape which is conventionally typical AV  
recording media.

#### (Description of DVD-RAM)

In recent years, an enhancement in the density of a writable  
25 optical disc has been developed so that it has been possible to record video

data as well as computer data and audio data.

For example, a convexo-concavo shaped guide groove has conventionally been formed on the signal recording face of the optical disc. While a signal has conventionally been recorded on only a land portion or a groove portion, it has become possible to record the signal on both the land and groove portions by a land-groove recording method. Consequently, a recording density has been enhanced by approximate twice as much (see Japanese Patent Laid-Open Publication No. 8-7282, for example). Moreover, there has also been devised and practically used a zone CLV method or the like in which the control of a CLV method (constant linear velocity recording) effective in an enhancement in the recording density can be simplified and easily used practically (see Japanese Patent Laid-Open Publication No. 7-93873, for example).

A great problems in the future are how to record AV data including video data using an optical disc intended to have an increase in a capacity, and how to implement performance greatly exceeding a conventional AV apparatus and new functions.

By the appearance of such a writable optical disc having a large capacity, it can be supposed that an optical disc becomes a mainstream also for AV recording and reproduction in place of a conventional tape. The conversion of recording media from the tape into the disc has various influences on the function and performance of an AV apparatus. The conversion into the disc has the greatest feature that random access performance is considerably enhanced. If the tape is subjected to random access, it is necessary to usually take a time in order of several minutes for one rewinding. This is extraordinarily late as

compared with a seek time (20-60 ms or less) on the optical disc media. Accordingly, the tape cannot act as a random access device in respect of practical use. By such random access performance, the distributed recording operation of the AV data which could not be performed by the conventional tape  
5 can be implemented by the optical disc.

Fig. 34 is a block diagram showing a drive device of a DVD recorder. In the drawing, the reference numeral 11 denotes a optical pick-up for reading the data of a disc, the reference numeral 12 denotes an ECC (error correcting code) processing section, the reference numeral 13 denotes a track  
10 buffer, the reference numeral 14 denotes a switch for switching the input and output to and from the track buffer, the reference numeral 15 denotes an encoder, and the reference numeral 16 denotes a decoder. The reference numeral 17 denotes a enlarged part of the disc.

As shown by the reference numeral 17, data are recorded on the  
15 DVD-RAM disc with 1 sector = 2KB as a minimum unit. Moreover, an error correcting processing is executed by the ECC processing section 12 with 16 sectors = 1 ECC block.

The track buffer shown by the reference numeral 13 serves to record the AV data with a variable bit rate in order to record the AV data on the  
20 DVD-RAM disc more efficiently. While a read/write rate ( $V_a$  in the drawing) from/to the DVD-RAM is a fixed rate, the AV data change a bit rate ( $V_b$  in the drawing) according to the complexity of the contents thereof (a video image, for example). The track buffer 13 serves to absorb a difference in the bit rate. For example, this is not required if the AV data is set to the fixed bit rate as in a  
25 video CD.

By utilizing the track buffer 13 still effectively, the AV data can be discretely provided on the disc. Description will be given with reference to Fig. 35.

Fig. 35A is a diagram showing an address space on a disc. In the case where the AV data are separately recorded in a continuous region of [a1, a2] and a continuous region of [a3, a4] as shown in Fig. 35A, the AV data can be continuously reproduced by supplying data stored in the track buffer 13 to the decoder 16 while a seek is being carried out from a2 to a3. A status obtained at this time is shown in Fig. 35B.

The AV data read from a1 are input to the track buffer 13 and output from the track buffer 13 at a time t1, and the data are stored in the track buffer 13 by a rate difference ( $V_a - V_b$ ) between an input rate ( $V_a$ ) to the track buffer 13 and an output rate ( $V_b$ ) from the track buffer 13. This state continues up to a2 (time t2). When an amount of data stored in the track buffer 13 for this period of time is represented by  $B(t_2)$ , it is sufficient that amount  $B(t_2)$  stored in the track buffer 13 can be consumed to continuously supplied to the decoder 16 till a time t3 corresponding to data reading start point of a3.

In other words, if a constant amount of data ([a1, a2]) to be read before the seek or more are kept, the AV data can be continuously supplied even if the seek is generated.

In the above example the description is given to the case where the data are read from the DVD-RAM (that is, playback), however the case where the data is written to the DVD-RAM (that is, picture recording) may be considered similarly.

If the constant amount or more of data are continuously recorded

on the DVD-RAM as described above, continuous reproduction / picture recording can be carried out even if the AV data are distributed and recorded on the disc.

## 5 (Description of MPEG)

Next, description will be given to the AV data.

As described earlier, the AV data to be recorded on the DVD-RAM use an international standard referred to as MPEG (ISO / IEC13818).

Even a DVD-RAM having a large capacity of several GBs does not always have a sufficient capacity for exactly recording non-compressed digital AV data. Therefore, a method for compressing and recording the AV data is required. As a method for compressing the AV data, the MPEG (ISO / IEC13818) has widely spread in the world. In recent years, the LSI technology has been improved so that MPEG codec (expansion / compression LSI) has been put into practical use. Consequently, the DVD recorder can implement MPEG expansion / compression.

The MPEG mainly has the following two features in order to implement highly efficient data compression.

A first feature is that a compressing method using a time correlation characteristic between frames is introduced in addition to a compressing method using a space frequency characteristic which has conventionally been carried out in the compression of the motion picture data. In the MPEG, each frame (which will be also referred to as a picture in the MPEG) is classified into three kinds of parts, that is, an I picture (intra-frame coding picture), a P picture (a picture using the intra-frame coding and a

reference relationship in the past) and a B picture (a picture using the intra-frame coding and reference relationships in the past and future), thereby performing data compression.

Fig. 36 is a diagram showing a relationship among the I, P and B pictures. As shown in Fig. 36, the P picture refers to the last I or P picture in the past, and the B picture refers to the closest I or P picture in the past and future. As shown in Fig. 36, moreover, since the B picture refers to the I or P picture in the future, the display order (display order) of each picture and the order (coding order) on the compressed data may be coincident with each other.

A second feature of the MPEG is that coding amount can be assigned dynamically for each picture in accordance with the complexity of the picture. The decoder of the MPEG comprises an input buffer. The decoder can assign a large coding amount to a complex picture which is hard to compress by storing data in the decoder buffer in advance.

Audio data used by the DVD-RAM can be selected for use from three kinds of parts, that is, MPEG audio for carrying out data compression, Dolby digital (AC-3) and non-compressed LPCM. While the Dolby digital and the LPCM have a fixed bit rate, the MPEG audio has a variable bit rate and has a size which is not as great as the size of a video stream but can be selected from plural kinds of sizes in an audio frame unit.

Such AV data are multiplexed into one stream by a method referred to as an MPEG system. Fig. 37 is a diagram showing the structure of the MPEG system. The reference numeral 41 denotes a pack header, the reference numeral 42 denotes a packet header, and the reference numeral 43 denotes a payload. The MPEG system has a hierarchical structure which is

referred to as a pack and a packet. The packet comprises the packet header 42 and the payload 43. The AV data are divided per proper size from the head, and are stored in the payload 43. The packet header 42 stores ID (stream ID) for identifying stored data, a decoding time DTS (Decoding Time Stamp) of data (the DTS is omitted if the decoding and the display are carried out at the same time as in the audio data) and a presentation time PTS (Presentation Time Stamp) of the data which are included in the payload represented with a precision of 90 kHz are recorded, as information related to AV data stored in the payload 43. The pack is a unit having a plurality of packets together. In case of the DVD-RAM, one pack is used every packet. Therefore, the pack comprises the pack header 41 and the packet (the packet header 42 and the payload 43). The pack header stores SCR (System Clock Reference) representing with a precision of 27 MHz a time that data in the pack are input to the decoder buffer.

In the DVD-RAM, such an MPEG system stream is recorded by using one pack as one sector (= 2048 B).

Next, description will be given to a decoder for decoding the above-mentioned MPEG system stream. Fig. 38 shows a decoder model (P-STD) of the MPEG system decoder. The reference numeral 51 denotes an STC (System Time Clock) acting as a reference time in the decoder. The reference numeral 52 denotes a demultiplexer for decoding or demultiplexing a system stream. The reference numeral 53 denotes an input buffer of a video decoder. The reference numeral 54 denotes a video decoder. The reference numeral 55 denotes a reorder buffer for temporarily storing the I and P pictures to absorb a difference between the data order and the display order which is made between the I and P pictures and the B picture as described above. The

reference numeral 56 denotes a switch for adjusting the order of the outputs of the I and P pictures stored in the reorder buffer and the B picture. The reference numeral 57 denotes an input buffer of an audio decoder. The reference numeral 58 denotes an audio decoder.

5           Such an MPEG system decoder serves to process the above-mentioned MPEG system stream in the following manner. At a time that the time of the STC 51 is coincident with the SCR described in the pack header, the demultiplexer 52 inputs the same pack. The demultiplexer 52 serves to interpret a stream ID in the packet header and to transfer the data of the  
10       payload to the decoder buffer for each stream. Moreover, the demultiplexer 52 fetches the PTS and the DTS in the packet header. The video decoder 54 fetches picture data from the video buffer 53 at a time that the time of the STC 51 is coincident with the DTS to carry out a decode processing, and stores the I and P pictures in the reorder buffer 55 and displays the B picture. While the I and P pictures are decoded by the video decoder 54, the switch 56 is  
15       connected to the reorder buffer 55 to output a previous I or P picture in the reorder buffer 55. While the B picture is decoded, the switch 56 is connected to the video decoder 54. The audio decoder 58 fetches and decodes data for one audio frame from the audio buffer 57 at a time that the time of the STC 51 and  
20       the PTS (there is no DTS in cast of audio) are coincident with each other in the same manner as the video decoder 54.

Next, description will be given to a method for multiplexing the MPEG system stream with reference to Figs. 39A-39D. Fig. 39A shows a video frame, Fig. 39B shows a status in the video buffer, Fig. 39C shows the MPEG  
25       system stream, and Fig. 39D shows audio data. An axis of abscissa indicates a

time base which is common to each drawing, and each drawing is represented on the same time base. As shown in Fig. 39B, moreover, an axis of ordinate indicates a buffer usage (the data storage amount of the video buffer), and a thick line in the drawing indicates a transition of the buffer usage on a time basis. Furthermore, the gradient of the thick line is equivalent to the bit rate of the video, and indicates that data are input to the buffer at a constant rate. A reduction in the buffer usage at a constant interval indicates that the data are decoded. Besides, the intersection of an oblique dotted line and the time basis indicates a time that the data transfer of the video frame to the video buffer is started.

Hereinafter, a complex image A in the video data will be described as an example. Since an image A requires a large coding amount as shown in Fig. 39B, the data transfer to the video buffer should be started at a time  $t_1$  in the drawing in place of the decoding time of the image A. (A time from the data input start time  $t_1$  till the decoding will be referred to as  $vbv\_delay$ ). As a result, the AV data are multiplexed in the position (time) of the video pack shown in an oblique line. On the other hand, the transfer of the audio data which does not require dynamic coding amount control differently from the video data does not need to be particularly made earlier than the decode time. For this reason, generally, the multiplexing is carried out a little before the decode time. Accordingly, the video data and the audio data which are reproduced at the same time are multiplexed in the state in which the video data are preceded. In the MPEG, a time that data can be stored in the buffer is restricted, and all the data but still picture data are defined such that they should be output from the buffer to the decoder within one second after they are input to the buffer. For

this reason, a shift of the multiplexing of the video data and the audio data is one second at the maximum (strictly speaking, there is a further shift by the reorder of the video data).

While the video has been followed by the audio in this example, the audio can also be followed by the video in respect of theory. When a simple picture having a high compression ratio is prepared for the video data and the audio data are transferred unnecessarily quickly, such data can be created intentionally. However, the precedence can be given within one second at the maximum based on the restrictions of the MPEG.

#### (Description of Tape Media)

Next, description will be given to tape media.

Fig. 40 is a diagram illustrating a relation between a tape and a tape recorder (recording head). As shown in the figure, recording areas for video data and audio data are separately provided in parallel with a tape running direction. Therefore it is easy to record audio data independently. In conventional analog video tape recorder, reproduction and recording can be carried out simultaneously with one head since delay time from reproduction to recording is almost zero.

DVD-RAM expected as the next generation AV recording media for example has the following problems.

The biggest problem to after-recording operation in DVD recorder is caused by an MPEG stream which is AV data to be recorded by the DVD recorder and the difference of mechanism between a video recorder and the DVD recorder.

In the video recorder, as described in the prior art, each of video and audio channels is independently recorded on a tape. The after-recording operation of an audio can easily be carried out because there is no delay from playback to sound recording. In the DVD recorder, however, a video and an audio are recorded in one multiplexed stream. One optical pick-up is used for reading and writing operations. A time difference is made from playback to recording, since one track buffer is provided for implementing a variable bit rate. Even though two optical pick-ups are provided, they should be operated independently. Even if each of the optical pick-ups can be operated independently, the recording and playback operations cannot be carried out at the same time in the DVD-RAM for changing a rotating speed for each zone when a region to be accessed by each of the pick-ups is provided across different zones.

As described in the prior art, a time stamp for AV synchronous playback is described on the MPEG stream. Therefore, in the case where a time stamp to be given to an audio stream to be recorded later is inconsistent with a time stamp given to an existing stream, a decoder is not normally operated in some cases. For example, in the case where an SCR given to a video pack in the existing stream and an SCR given to an audio pack recorded later have the same time, two data to be processed on the time of the SCR by the decoder are simultaneously present. Consequently, the decoder cannot be normally operated. Thus, there is a problem in that the worst hang up is caused.

DVD-RAM can store audio streams in various kinds of format. The DVD recorder can not know whether the DVD recorder can apply after-record operation to the DVD-RAM in which data has been recorded by other

recorders. Therefore stream must be analyzed at start of data recording.

## SUMMARY OF THE INVENTION

5 This invention is directed to provide information recording medium which actualize easy determination of possibility of after-recording on the recording medium. This invention is also directed to provide an apparatus and a method for recording data to such a recording medium.

10 In a first aspect of the invention, a recording medium comprises an audio stream capable of being replaced with an after-recorded audio stream; and audio attribute information including bit rate information indicative of a bit rate of the audio stream. In the recording medium, a plurality of audio streams may be stored therein. At least one of the plurality of audio streams may be the audio stream capable of being replaced with an after-recorded audio stream. The audio stream capable of being replaced with an after-recorded audio stream may be one audio stream which is provided for the other audio stream carrying original audio data and has same audio attribute as the other audio stream.

20 In a second aspect of the invention, an apparatus is provided for performing after-recording to audio stream recorded on the recording medium according to the invention. The apparatus comprises a checking section for checking possibility of after-recording operation to the recorder before after-recording operation starts, and an operation section for performing the after-recording operation.

25 In a third aspect of the invention, a method is provided for performing after-recording to audio stream recorded on the recording medium

according to the invention by using a recording apparatus. The method comprises referring to the bit rate information in the audio attribute information, determining whether or not the apparatus is able to encode the audio stream to be after-recorded in bit rate of the bit rate information, and deciding that the apparatus to be able to perform after-recording when the apparatus is determined to be able to encode the audio stream in the bit rate.

In accordance with the present invention, it is possible to determine whether or not the after-recording operation to audio stream can be performed. Therefore, the recorder, for example, gives warning to user when the recorder does not have enough ability to process the audio stream for after-recording.

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS.

25 The present invention will be described in detail by using a DVD

recorder and a DVD-RAM according to an embodiment of the present invention.

<First Embodiment>

(Logical Structure on DVD-RAM)

5 First of all, the logical structure on the DVD-RAM will be described with reference to Figs. 41A and 41B. Fig. 41A shows a data structure on a disc seen through a file system, and Fig. 41B shows a physical sector address on a disc.

10 The head portion of the physical sector address has a lead-in region which stores a reference signal necessary for stabilizing a servo, an identification signal with other media and the like. A data region is provided following the lead-in region. In this portion, logically effective data are recorded. Finally, a lead-out region is provided and stores the same reference signal as in the lead-in region and the like. A management information for the file system  
15 which is referred to as a volume information is recorded on the head of the data region. Since the file system is not directly related to the contents of the present invention, the description of it will be omitted.

Through the file system, the data in the disc can be dealt with as a directory or a file as shown in Fig. 41A. All the data to be dealt with by the DVD  
20 recorder are put on a VIDEO\_RT directory under a ROOT directory as shown in Fig. 41A. A file to be dealt with by the DVD recorder is roughly classified into two kinds, that is, one management information file and at least one AV file (ordinarily, a plurality of files).

25 (Management Information File)

Next, the contents of the management information file will be described with reference to Fig. 42A.

The management information file is roughly divided into a VOB table and a PGC table. VOB (Video Object) means a program stream of MPEG. PGC defines the playback order of Cell which uses any partial section (or all sections) in the VOB as one logical playback unit. In other words, the VOB is a unit which is significant as the MPEG, and the PGC is a unit at which a player plays back.

The VOB table stores the number of VOBs (Number\_of\_VOBs) and each VOB information therein. The VOB information comprises a corresponding AV file name (AV\_File\_Name), a VOB identifier in the disc (VOB\_ID), a start address in the AV file (VOB\_Start\_Address), an end address in the AV file (VOB\_End\_Address), a playback time length of the VOB (VOB\_Playback\_Time) and an attribute information of the stream (VOB\_Attribute).

A stream attribute information field comprises a video attribute (Video\_Attribute), a first audio stream attribute (Audio0\_Attribute) and a second audio stream attribute (Audio1\_Attribute). The audio stream attribute information comprises an audio coding mode (Coding\_Mode), an application flag (Application\_Flag), a quantization coefficient (Quantization), a sampling frequency (Sampling\_Frequency) and the number of audio channels (Number\_of\_channels).

The PGC table includes the number of PGCs (Number\_of\_PGCs) and each PGC information therein. The PGC information comprises the number of Cells (Number\_of\_Cells) in the PGC and each Cell information. The

cell information comprises corresponding VOB\_ID, a playback start time in the VOB (Cell\_Start\_Time), a playback time in the VOB (Cell\_Playback\_Time), a playback start address in the VOB (Cell\_Start\_Address), a playback end address in the VOB (Cell\_End\_Address), an audio flag (Audio\_Flag) for specifying that audio signal played back in the Cell is an original audio or a  
5 after-recording audio. The cell information further comprises Cell\_Start\_Address and Cell\_End\_Address for the after-recording audio.

(AV File)

10 Next, an AV file will be described with reference to Fig. 42B.

The AV file includes at least one VOB (ordinarily, a plurality of VOBs). The VOB is continuously recorded in the AV file. The VOB in the AV file is managed by the VOB information of the above-mentioned management information file. A player can access the VOB by first accessing the  
15 management information file to read out the start and end addresses of the VOB. Moreover, the Cell is defined as a logical playback unit in the VOB. The Cell is the partial playback section (or the whole sections) of the VOB and can be freely set by a user. By the Cell, it is possible to edit AV data simply without actual operation of the AV data. In the same manner as the VOB, an access  
20 information about the Cell is managed in the Cell information in the management information file. The player can access the Cell by first accessing the management information file to read out the start and end addresses of the Cell.

The address information of the Cell is based on the VOB and the  
25 address information of the VOB is based on the AV file. Therefore, the player

actually accesses the AV file by adding the address information of the VOB to the address information of the Cell to calculate an address information in the AV file.

## 5 (Structure of VOB)

Fig. 43 is a diagram showing the structure of the VOB according to the present embodiment.

Two audio streams are set to an audio stream #1 and an audio stream #2, respectively. As shown in Fig. 43, the same audio stream is stored  
10 in the audio stream #1 and the audio stream #2.

It is to be noted that the audio streams are not simply identical as streams but are identical in pack and packet units. The value of SCRs (System Clock References) of a pack header, the value of stream numbers of a packet header and the value of original\_or\_copy are different. However, other fields,  
15 for example, PST and the like have the same values. Of course, the contents of a payload are identical.

The fields of original\_or\_copy are different in order to explicitly indicate, in the streams, that the stream #1 is an original stream and the stream #2 is a dummy stream for the after-recording operation. The flags may have the  
20 same values.

By putting such two audio streams in the VOB, one of the original audio data can remain even if one of the audio streams is recorded by the after-recording operation as shown in Fig. 44.

For the following purpose, the two audio streams are put in. A  
25 recording region for the after-recording operation, that is, a recording band is

kept. In addition, if the attribute of the audio stream to be after-recorded, that is, a coding mode and a bit rate are set identical to that of the audio stream recorded in a dummy, a pack and a packet header become completely identical and the after-recording operation can be carried out only by exchanging the contents of the payload.

This means that even though the system encoder of the MPEG should carry out the multiplexing operation of the audio pack so that an audio buffer neither underflows nor overflows, the multiplexing operation can be omitted on the after-recording operation.

When the after-recording operation is to be carried out in various coding modes and bit rates, the audio pack should be replaced not only to ensure a band but also to prevent the overflow and underflow of the audio buffer. Therefore, it is impossible to simply ensure the replacement of the audio pack between sets having different algorithms.

In the present embodiment, the SCR and the PTS are not changed in the same coding mode and the same bit rate but data are rewritten in a pack unit such that only the contents of the audio payload are replaced.

Of course, while the contents of the pack header and the packet header including the SCR and the PTS may be rewritten, it is apparent that the completed stream should satisfy the conditions of the MPEG stream.

Next, the reason why the same audio data are to be recorded in the stream #1 and the stream #2 will be described with reference to Fig. 45.

For example, in the case where a part of the VOB is to be after-recorded, when the data recorded as the stream #2 are silent or have insignificant contents, for example, insignificant data and significant data are

switched each other on the boundary between a after-recorded portion and a non-after-recorded portion.

Since the DVD recorder has only one audio decoder, the stream #1 and the stream #2 cannot be played back at the same time. Accordingly, when the partial after-recording operation is to be carried out, it is necessary to designate the audio stream to be played back to a decoder so as to switch the audio stream from original data to after-recorded data or from after-recorded data to original data on the boundary portion. The audio stream to be played back is generally designated by control from the host side, that is, a microprocessor. Therefore, it is hard to designate the switching in a frame unit.

By recording the same audio data as the original on the dummy audio stream itself as shown in Fig. 45, it is also possible to continuously play back on the boundary portion where the partial after-recording operation is executed.

The above-mentioned problem of the partial after-recording operation can be solved when the audio streams are not completely identical but have the same contents, that is, are data having the same contents as analog data during the playback. Description will be given to the reason why two completely identical streams are required to be recorded.

When the user wants to turn back the after-recorded audio data (that is, to erase the audio data) after the partial after-recording operation, it is necessary to record some data again because the overwritten data cannot be turned back. When the silent audio stream is to be recorded, the above-mentioned problem of the partial after-recording operation is caused when the user tries the after-recording operation again in the partial section of the silent

audio stream section.

In the case where the two identical audio streams are used in the pack and packet units except the SCR and the stream number as shown in Fig. 46, an original state can be restored by copying data in the packet unit from the stream #1 to the stream #2. At this time, it is apparent that the stream number in the packet header should be modified.

#### (State of Audio Stream #2)

Fig. 47 is a diagram showing the state of the stream #2 recorded for the after-recording operation described above. The state of the stream #2 is divided into "same audio stream", "stream having the same audio contents", "after-recorded stream" and "individual stream". As described above, it is possible to carry out the after-recording operation from the same audio stream and the stream having the same audio contents. On the contrary, it is possible to return only to the same audio stream. That is, it is possible to return from the after-recorded audio stream to the same stream.

Moreover, the after-recorded stream can be regarded as an independent stream. In the independent stream (for example, the audio stream #2 in which silent data are recorded), the after-recording operation can be carried out for the whole VOB. However, the partial after-recording operation of the VOB causes the above-mentioned problem.

The above-mentioned state is managed in Application Flag on the DVD-RAM disc.

(Structure of DVD recorder)

Next, the structure of the DVD recorder will be described with reference to Fig. 48.

In the drawing, the DVD recorder comprises a user interface 7801, a system controller 7802, an input section 7803, an encoder 7804, an output section 7805, a decoder 7806, a track buffer 7807 and a drive 7808. The user interface 7801 transfers data displayed to the user or accepts a request from the user. The system controller 7802 serves to wholly perform management and control. The input section 7803 including an AD converter inputs video and audio data. The output section 7805 outputs a video and audio data. The decoder 7806 decodes an MPEG stream.

(Recording Operation of DVD recorder)

The recording operation of the DVD recorder will be described.

The user interface 7801 first accepts a request from the user. The user interface 7801 transmits the request from the user to the system controller 7802. The system controller 7802 interprets the request from the user and gives a process request to each module. When the user gives a request for picture recording, the system controller 7802 gives a request for encoding to the encoder 7804.

The encoder 7804 carries out video encoding, audio encoding and system encoding for video and audio information sent from the input section 7803, and transfers the encoded data to the track buffer 7807.

Next, the system controller 7802 gives, to the driver 7808, a request for writing data stored in the track buffer, and the drive 7808 fetches data from the track buffer and records the fetched data in the DVD-RAM.

The user's request for stop is transmitted to the system controller 7802 through the user interface 7801. The system controller 7802 gives a request for encoding stop to the encoder 7804, and the encoder 7804 stops an encoding process when the data are completely encoded and informs the system controller 7802 of encoding termination.

Then, the system controller 7802 gives a request for a writing termination to the drive 7808, and the drive 7808 stops reading and writing data to the DVD-RAM when the track buffer 7807 becomes empty.

Finally, the system controller 7802 modifies an AV file information, a clip sequence information and a file system information for the recorded VOB, and records them in the DVD-RAM through the drive 7808. In particular, a value of Application Flag is recorded as the same audio stream.

For the recording operation, it is important that two audio streams are inserted into the outputting VOB in the encoder 7804, while one audio data is input.

A process of inserting the two audio streams will be described with reference to Fig. 49. Fig. 49 is a diagram showing the structure of the encoder. As shown, the encoder comprises a video encoder 7804a, an audio encoder 7804b and a system multiplexer 7804c.

The video encoder 7804a encodes an input video signal into an MPEG video stream. The audio encoder 7804b encodes an input audio signal into an audio stream. At this time, there is one audio stream. Next, the multiplexer 7804c performs packing, packetizing and multiplexing the video stream and audio stream. In the multiplexing process, copy is carried out in an audio pack unit and the multiplexing is executed for the two audio streams.

The audio stream may be copied in a form of a packet, or in a form of a payload immediately before the packetizing process. As described above, the two audio streams are inserted into the VOB.

5 (After-recording operation of the DVD recorder)

Next, description will be given to the after-recording operation in the DVD recorder.

First of all, description will be given to the input and output of AV data on the after-recording operation by the DVD recorder. In the input and  
10 output of the AV data, data are read or written in a unit called an AV block.

The AV block indicates the continuous recording region shown in Fig. 35. When the continuous recording region is much greater than a continuous recording length necessary for seeking the continuous recording region, it may be divided into small regions as AV blocks.

15 Subsequently, the track buffer 7807 is divided into track buffer1 and track buffer3 to be used for playback and track buffer2 and track buffer4 to be used for recording. This state is illustrated in Fig. 50.

The input and output of the track buffer will be described in time series with reference to Fig. 52.

20 Description will be given by taking, as an example, the case where the VOB is constituted by four AV blocks A, B, C and D as shown in Fig. 52B.

Fig. 52A is a diagram representing the buffer storage amounts of the track buffers 1, 2, 3 and 4 on a time base. At the track buffer1 (TB1) and the track buffer3 (TB3), the data storage amount is increased because data are  
25 input from the drive, that is, data are read out for playback from the DVD-RAM,

and the data storage amount is decreased because data are supplied to the decoder.

On the contrary, at the track buffer2 (TB2) and the track buffer4 (TB4), the data storage amount is increased because data are input from the encoder after the after-recording operation, that is, data are recorded (overwritten) on the DVD-RAM, and the data storage amount is decreased because data are supplied to the drive for recording in the DVD-RAM.

During period T1 in the drawing, first, the AV block A is read out on the track buffer1 and the after-recording operation starts immediately after the data are read out. During period Ta, the after-recording operation is carried out for the AV block A. The after-recorded data of the AV block A are recorded on TB2. Therefore, the storage amount of the TB2 is increased during the period Ta.

The drive reads the next AV block B immediately after the period T1. The AV block A and the AV block B are not present on the same continuous recording region, and therefore the AV block B is read out after the seeking of a head (period T2).

After the after-recording operation of the AV block A is ended, the after-recording operation of the AV block B then starts (period Tb). The data of the AV block B stored in the track buffer3 are supplied to the decoder. The data after-recorded through the encoder are stored in the track buffer4 during the period Tb.

Immediately after the after-recording operation of the AV block A is ended, the drive overwrites the after-recorded data of the AV block A stored in the track buffer2 onto the AV block A (period T3).

When the overwriting process on the AV block A is completed, the drive then reads out the AV block C. The read data on the AV block C are stored in the track buffer1 (period T4).

5 By repeating the above-mentioned operation, the after-recording process can be carried out.

Next, description will be given to a process flow in the DVD recorder.

The user's request for the after-recording operation is transmitted to the system controller 7802 through the user interface 7801. First of all, the  
10 system controller 7802 gives, to the drive 7808, a request for reading out the VOB to be after-recorded.

The drive 7808 reads out the VOB to be after-recorded from the DVD-RAM in an AV block unit and records the read VOB in the track buffer1.

At the same time, the system controller 7802 gives a request for  
15 the after-recording process to the encoder 7804.

The encoder 7804 performs the audio-encoding of audio data input from the input section 7803, reads out an audio pack including the audio stream #2 in the stream sent from the decoder, replaces a payload with the encoded after-recording audio stream, and records the after-recording audio  
20 stream in the track buffer2. This state is shown in Fig. 51.

When the after-recording process of the AV data stored in the track buffer1 is completed, the encoder 7804 consecutively starts the after-recording process of the AV data recorded in the track buffer3 and notifies the system controller 7802 that the after-recording process of the track buffer1 is  
25 ended.

Next, the system controller 7802 gives, to the drive 7808, a request for writing the data of the track buffer 2.

The drive 7808 overwrites and records the data of the track buffer 2 on the DVD-RAM after the completion of writing into the track buffer3.

5 By sequentially carrying out the above-mentioned processes for the track buffer1, the track buffer2, the track buffer3 and the track buffer4 as described above, the after-recording operation can be executed.

Moreover, when the VOB is completely read out from the DVD-RAM, the drive 7808 informs the system controller 7802 of termination of the  
10 VOB reading process.

The system controller 7802 gives a request for termination of after-recording to the encoder 7804. The encoder 7804 carries out the after-recording process until the after-recording processes of all the audio data remaining in the track buffer1 and the track buffer3 are terminated. The  
15 encoder 7804 informs the system controller 7802 of the after-recording termination when the after recording processes of all the data are completed.

Next, the system controller 7802 gives a request for a writing end process to the drive 7808. The drive 7808 overwrites and records all the VOB data remaining in the track buffer2 and the track buffer4 on the DVD-RAM disc  
20 and informs the system controller 7802 that the after-recording process is completed after the completion of recording operation.

The system controller 7802 changes the Application Flag to the "after-recorded" and carries out the recording operation on the DVD-RAM through the drive 7808 again.

(Playback (Reproduction) Operation of DVD recorder)

Next, the playback operation of the DVD recorder will be described.

5 The user's request for a playback process is transmitted to the system controller 7802 through the user interface 7801. The system controller 7802 gives a request for reading the VOB to the drive 7808, and the drive 7808 reads out the VOB data from the DVD-RAM and transfers the VOB data to the track buffer 7807.

10 Then, the system controller 7802 gives a request for playing back the VOB to the decoder 7806, and the decoder 7806 reads out data from the track buffer 7807, decodes the read data and outputs the decoded data through the output section 7805.

When the VOB is completely read out, the drive 7808 informs the system controller 7802 of termination of the reading process, and the system controller 7802 gives a request for ending the playback to the decoder 7806. 15 The decoder 7806 carries out the reading and decoding operations of the data until the data of the track buffer 7807 becomes empty, and informs the system controller 7802 of the end of the playback operation after the completion of decoding process for all data.

20 At this time, the following is important. In the case where the user gives a request for switching the audio stream, that is, a request for playing back the audio stream #2, the system controller 7802 informs the user through the user interface 7801 that the switching is impossible, without playing back the audio stream #2 when the value of the Application Flag indicates the same 25 audio streams or the same audio contents.

When the same audio streams or the same audio contents are recorded in the audio stream #2, error message is displayed for the user. This prevents the user from thinking that the switching is failed or the DVD recorder is out of order, because the user performing the switching operation of the audio stream expects the playback of an audio stream different from the audio stream #1, however just the same audio is played back in this case even if audio stream to be played back is switched to the audio stream #2.

While the audio stream 2 has been a dummy audio stream for the after-recording operation in the present embodiment, the audio stream 1 may be the dummy audio stream for the after-recording operation.

The payloads in the packets between the two audio streams have been coincident with each other in the present embodiment. The sizes of the audio data to be packetized may be different from each other, and may be identical to the audio streams recorded in the completed VOB or have the same contents as the audio streams recorded in the completed VOB.

In the present embodiment, furthermore, restrictions may be put on that the audio pack of the audio stream #1 always comes earlier between the corresponding audio packets between the two audio streams or the audio pack of the audio stream #2 may be arranged immediately after the audio pack of the audio stream #1. By putting such restrictions, it is easy to find the audio pack of the audio stream #2 during the after-recording operation. Moreover, restrictions can be put on that the audio stream #2 precedes the audio stream #1.

Moreover, there have been four kinds of values of the Application Flag, that is, "the same audio stream", "the stream having same audio contents", "the after-recorded stream" and "the individual stream". The "same audio

stream" and the "same audio contents" may be dealt with as one state, the "after-recorded stream" and the "individual stream" may be dealt with as one state. Also the "same audio stream", "stream having same audio contents" and "after-recorded stream" may be dealt with as one state.

5                Furthermore, although four track buffers have been provided in the description of the after-recording operation, the AV data may be overwritten on the track buffers by sharing the track buffer1 and track buffer2, and by sharing the track buffer3 and track buffer4, respectively.

#### 10        <Second Embodiment>

              It has been possible to implement the after-recording operation which is hard to perform in the DVD and the DVD recorder in the first embodiment. However, the DVD and the DVD recorder further have the following problem.

15                Different from the conventional tape media, the DVD can carry out recording in various audio stream formats. This causes the after-recording operation in the DVD recorder to be hard to perform.

              Concretely, the audio stream which can be recorded in the DVD has three kinds of formats of AC-3, MPEG audio and linear PCM. Moreover,  
20                there are various modes such as recording channel numbers, a recording bit rate and the like in individual formats.

              On the other hand, a general audio encoder rarely can operate with all encode modes, channel numbers and bit rates, and can operate with only a mode suitable for each merchandise target. In other words, when the  
25                after-recording operation is applied to the disc on which data have been

recorded by the other DVD recorder, the after-recording operation should be actually started or the recorded audio stream should be analyzed in order to decide whether the after-recording operation is operable or not.

DVD and DVD recorder in this embodiment have basically same structure as in the first embodiment, and are characterized by a method of having a management information on the disc and the operation of a recorder for performing the after-recording process. In the present embodiment, the difference from the first embodiment will be mainly described.

#### 10 (Logical Structure of DVD - RAM)

First of all, the logical structure of the DVD-RAM will be described with reference to Fig. 1. Fig. 1 shows a physical sector address on a disk and a data structure on the disk which can be seen through a file system.

All the data to be dealt with by the DVD recorder are put on a DVD\_RTR directory immediately under a ROOT directory as shown in Fig. 1. The file to be dealt with by the DVD recorder is roughly divided into 2 kinds of files, that is, one management information file and at least one AV file (ordinary a plurality of AV files). The AV file stores an RTR\_MOV.VRO file for storing a motion picture and an RTR\_STO.VRO file for storing a still picture and audio data which are recorded at the same time with the motion picture or the still picture.

Fig. 2 is a diagram showing the structure of the RTR\_MOV.VRO file having motion picture. As shown in Fig. 2, M\_VOB (Movie Video Object) which is the program stream of MPEG is provided in the RTR\_MOV.VRO file in order of picture recording.

The M\_VOB comprises a VOB (Video Object Unit) in which one unit is 0.4 to 1.0 second based on a video reproducing time. The VOB comprises V\_PCK (Video Pack), A\_PCK (Audio Pack) and SP\_PCK (Sub-picture Pack). Each pack is constituted in a 2 KB unit.

5           Video data in the VOB also comprises at least one GOP (Group of Pictures). The GOP is the decode unit of the MPEG video and includes a plurality of P pictures and B pictures with the I pictures in a head.

Fig. 3 is a diagram showing the structure of the RTR\_STO.VRO file in which a still picture and audio data are recorded. As shown in Fig. 3, S\_VOB (Still Picture Video Object) which is an MPEG program stream for the still picture is recorded in the RTR\_STO.VRO file in order of picture recording.

A great difference between the M\_VOB and the S\_VOB is that motion picture data and audio data are not mutually multiplexed but audio data (Audio part) are successively recorded after the still picture data (Video part), in addition to the recording of the still picture data in place of the motion picture data. Moreover, the S\_VOB is constituted by one VOB. The VOB comprises the V\_PCK, the A\_PCK and the SP\_PCK.

(AV data and Management Information)

20           Next, description will be given to the relationship between the M\_VOB and S\_VOB described above with reference to Fig. 4 and management information.

As described above, AV data have two kinds of data, that is, the M\_VOB for a motion picture and S\_VOB for a still picture. Each M\_VOB has management information M\_VOBI. Attribute information of the corresponding

25

M\_VOB is recorded in M\_VOBI. In case of the S\_VOB, when management is carried out for each S\_VOB, the amount of the management information gets increased. Therefore, management information S\_VOGL is provided for each group S\_VOG having a lump of S\_VOBS. S\_VOGL stores the attribute  
5 information of a corresponding S\_VOB group.

It is important that the data of the MPEG stream have no linearity between a time and a data amount. As described above, a compressing method using a time correlation characteristic and compression using a variable length coding method which is referred to as VBR are executed in order to  
10 implement highly efficient compression in the MPEG stream. Therefore, the time and the data amount, that is, address information do not uniquely correspond to each other.

The M\_VOBI has a filter (TMAP) for converting a time and an address. The S\_VOGL has a filter (S\_VOB Entries) for converting still picture  
15 number and an address in the group.

Next, description will be given to the management information of a playback sequence.

The playback sequence is defined as a sequence (PGC) of a cell indicative of a partial or whole interval of the M\_VOB and the S\_VOG. The  
20 playback sequence has two kinds of parts, that is, an original PGC and a user-defined PGC. The original PGC refers to all the AV data in the disc. The user-defined PGC defines a playback order of AV data which user selects in the disc (plural definitions can be obtained). The original PGC is also called a program set (Program Set), and includes a layer which is called a program (Program)  
25 having a plurality of cells logically bundled therebetween. The user-defined

PGC is also called a play list (Play List) and includes no Program therebetween differently from the original PGC.

(Management Information File)

5               Next, the contents of the management information file "RTR. IFO" will be described with reference to Figs. 5 to 33.

"RTR\_VMG" (Fig. 5):

Management information referred to as RTR\_VMG (Real Time Recording Video Management) is recorded in the RTR. IFO file. The  
10 RTR\_VMG comprises seven tables of RTR\_VMGI, M\_AVFIT, S\_AVFIT, ORG\_PGCI, UD\_PGCIT, TXTDT\_MG and MNFIT.

Next, each table will be described in detail.

"RTR\_VMGI" (Fig. 6):

RTR\_VMGI (Real Time Recording Video Management  
15 Information) comprises VMGI\_MAT and PL\_SRPT.

"VMGI\_MAT" (Fig. 6):

VMGI\_MT (Video Management Information Management Table) stores the following information as information related to the whole disc. A player and a recorder can first read the VMGI\_MAT to roughly obtain structural  
20 information of the disc.

VMG\_ID (Video Management Identifier):

VMG\_ID stores an identifier "DVD\_RTR\_VMG0" indicating that video recording data are recorded in this disc.

RTR\_VMG\_EA (RTR\_VMG End Address):

25               The end address of the RTR\_VMG is recorded therein.

**VMGI\_EA (VMGI End Address):**

The end address of the VMGI is recorded therein.

**VERN (Version Number):**

5 The version number of a recording format of the video recording data is recorded in accordance with a format shown in Fig. 7.

**TM\_ZONE (Time Zone):**

Recorded therein is a time zone to be used by all date and time information recorded in this disc. As shown in Fig. 7, TM\_ZONE comprises TZ\_TY (time zone type) and TZ\_OFFSET (time zone offset). TZ\_TY indicates  
 10 which one of the Greenwich mean time as a universal time and a standard time for each region is used for the reference of date information. TZ\_OFFSET records a time difference between the date and the Greenwich mean time.

**STILL\_TM (Still Time):**

15 A static time length obtained when displaying a soundless still picture is recorded.

**CHRS (Character Set Code for Primary Text):**

A character set code for a primary text which will be described below is recorded therein.

**M\_AVFIT\_SA (M\_AVFIT Start Address):**

20 Start address of M\_AVFIT is recorded therein. When M\_AVFIT is accessed, a seek is carried out up to this start address.

**S\_AVFIT\_SA (S\_AVFIT Start Address):**

Start address of S\_AVFIT is recorded therein. When S\_AVFIT is accessed, a seek is carried out up to this start address.

**25 ORG\_PGCI\_SA (ORG\_PGCI Start Address):**

Start address of ORG\_PGCI is recorded therein. When ORG\_PGCI is accessed, a seek is carried out up to this start address.  
UD\_PGCIT\_SA (UD\_PGCIT Start Address):

Start address of UD\_PGCIT is recorded therein. When UD\_PGCIT is accessed, a seek is carried out up to this start address.

TXTDT\_MG\_SA (TXTDT\_MG Start Address):

Start address of TXTDT\_MG is recorded therein. When TXTDT\_MG is accessed, a seek is carried out up to this start address.

MNFIT\_SA (MNFIT Start Address):

Start address of MNFIT is recorded therein. When MNFIT is accessed, a seek is carried out up to this start address.

"PL\_SRPT" (Fig. 8):

PL\_SRPT (Play List Search Pointer Table) is a table comprising PL\_SRPTI and n PL\_SRPs.

"PL\_SRPTI" (Fig. 8):

PL\_SRPTI (Play List Search Pointer Table Information) stores the following information for accessing to PL\_SRP.

PL\_SRP\_Ns (Number of PL\_SRP):

Number of PL\_SRPs is recorded therein.

PL\_SRPT\_EA (PL\_SRPT End Address):

End address of PL\_SRPT is recorded therein.

"PL\_SRP" (Fig. 8):

Moreover, the following information for giving access to the user - defined PGC which is actual data of the play list is recorded in PL\_SRP (Play List Search Pointer).

**PL\_TY (Play List Type):**

Any of the following values is recorded as a value for identifying the type of a play list in accordance with a description format shown in Fig. 9.

- 0000b : only motion pictures
- 5        0001b : only still pictures
- 0010b : hybrid of motion pictures and still pictures

**PGCN (PGC Number):**

PGC number corresponding to the play list is recorded therein. The PGC number indicates the recording order of PGC information in UD\_PGCIT which will be described below.

10

**PL\_CREATE\_TM (Play List Recording Date):**

Information about the date and time at which the play list was created is recorded therein in accordance with the description format shown in Fig. 9.

**PRM\_TXTI (Primary Text Information):**

15

Text information indicative of the contents of the play list is recorded therein. For example, in the case where a television program is picture recorded, the name of the program is recorded. Moreover, the primary text information is constituted by a field for the ASCII code and a field of a character code set specified by the above-mentioned CHRS.

20

**IT\_TXT\_SRPN (IT\_TXT\_SRP Number):**

When information indicative of the contents of the play list are optionally recorded as IT\_TXT in addition to the above-mentioned primary text, the IT\_TXT\_SRP number is recorded as link information to the IT\_TXT to be recorded in the TXTDT\_MG. The IT\_TXT\_SRP number indicates the recording

25

order in TXTDT\_MG which will be described below.

THM\_PTRI (Thumb Nail Pointer Information):

Thumb nail information which is representative of the play list is described.

5 "THM\_PTRI" (Fig. 8):

In THM\_PTRI is recorded the following information indicative of the position of a thumb nail.

CN (Cell Number):

Cell number of a cell including a thumb nail is recorded therein.

10 The cell number indicates the recording order of cell information in the UD\_PGCI to which the play list corresponds.

THM\_PT (Thumb Nail Point):

15 When a cell indicated by the above-mentioned CN is a motion picture cell, the display time of a video frame to be used as a thumb nail is recorded in accordance with a PTM description format shown in Fig. 10. The PTM is given in accordance with the reference time of a time stamp described in the MPEG program stream.

20 Moreover, when the cell indicated by the above-mentioned CN is a still picture cell, the still picture VOB entry number of a still picture to be used as the thumb nail is recorded in accordance with an S\_VOB\_ENTN description format shown in Fig. 11. The still picture VOB entry number indicates the recording order of the still picture VOB entry in a still picture VOB group indicated by this cell.

"M\_AVFIT" (Fig. 12):

25 M\_AVFIT (Motion picture AV File Information Table) stores

management information corresponding to motion picture AV file  
"RTR\_MOV.VRO" and comprises M\_AVFITI, M\_VOB\_STI and M\_AVFI.

"M\_AVFITI" (Fig. 12):

M\_AVFITI (Motion picture AV File Information Table Information)  
5 stores the following information necessary for giving access to M\_VOB\_STI and  
M\_AVFI.

M\_AVFI\_Ns (Number of Motion picture AV File Information):

Number of fields of succeeding AVFI information is indicated  
therein. When the value is "0", there exists no AVFI, while when the value is "1",  
10 there exists AVFI. Moreover, the presence of the AVFI also corresponds to that  
of RTR\_MOV.VRO which is the AV file for motion pictures.

M\_VOB\_STI\_Ns (Number of M\_VOB\_STI):

Number of fields of succeeding M\_VOB\_STI is indicated therein.

M\_AVFIT\_EA (M\_AVFIT End Address):

15 The end address of M\_AVFIT is recorded therein.

"M\_VOB\_STI" (Fig. 12):

M\_VOB\_STI (Movie VOB Stream Information) stores the following  
information as the stream information of movie VOB.

V\_ATR (Video Attribute):

20 The following video attribute information is recorded in accordance  
with a format shown in Fig. 13.

Video compression mode:

Any one of the following values for identifying a video  
compression mode is recorded therein.

25 00b : MPEG-1

01b : MPEG-2

**TV system:**

Any one of the following values for identifying a television system is recorded therein.

5                    00b : 525 / 60 (NTSC)

01b : 625 / 50 (PAL)

**Aspect ratio:**

Any one of the following values for identifying a resolution ratio is recorded therein.

10                   00b : 4 × 3

01b : 16 × 9

**line21\_switch\_1:**

Recorded therein is any one of the following values for identifying that closed caption data for a field 1 are recorded or not in a video stream.

15                   1b : Recorded

0b : Not recorded

**line21\_switch\_2:**

Recorded therein is any one of the following values for identifying that closed caption data for a field 2 are recorded or not in the video stream.

20                   1b : Recorded

0b : Not recorded

**Video resolution:**

Any one of the following values for identifying a video resolution is recorded therein.

25                   000b : 720 × 480 (NTSC), 720 × 576 (PAL)

001b : 702 × 480 (NTSC), 702 × 576 (PAL)

010b : 352 × 480 (NTSC), 352 × 576 (PAL)

011b : 352 × 240 (NTSC), 352 × 288 (PAL)

100b : 544 × 480 (NTSC), 544 × 576 (PAL)

5           101b : 480 × 480 (NTSC), 480 × 576 (PAL)

**AST\_Ns (Number of Audio Streams):**

Number of audio streams recorded in corresponding VOB is recorded therein.

**SPST\_Ns (Number of Sub-picture Streams):**

10           Number of sub-picture streams recorded in corresponding VOB is recorded therein.

**A\_ATR0 (Attribute of Audio Stream 0):**

The following audio attribute information corresponding to an audio stream 0 (corresponding to the audio stream #1 described above) is recorded in accordance with a format shown in Fig. 13.

15

**Audio coding mode:**

Any one of the following values for identifying an audio compressing method is recorded.

000b : Dolby AC-3

20           001b : MPEG audio having no extended stream

010b : MPEG audio having an extended stream

011b : linear PCM

**Application Flag:**

Any one of the following values for identifying application information is recorded therein.

25

00b : No application

01b : Mixed audio channel number

10b : With auxiliary voice

#### Quantization / DRC:

5            When using the MPEG audio, any one of the following values for identifying the presence of DRC (Dynamic Range Control) information is recorded therein.

00b : DRC data are not included in the MPEG stream.

01b : DRC data are included in the MPEG stream.

10           When using the LPCM audio, the following value for identifying the Quantization is recorded therein.

00b : 16 bits

#### fs:

15           The following value for identifying a sampling frequency is recorded therein.

00b : 48 kHz

#### Number of Audio channels:

Any one of the following values for identifying the number of audio channels is recorded therein.

20           0000b : one channel (monophonic)

0001b : two channels (stereo)

0010b : three channels

0011b : four channels

0100b : five channels

25           0101b : six channels

0110b : seven channels

0111b : eight channels

1001b : two channels (dual monophonic)

**Bitrate:**

5 Any one of the following values for identifying a bit rate is recorded therein.

0000 0001b : 64 kbps

0000 0010b : 89 kbps

0000 0011b : 96 kbps

10 0000 0100b : 112 kbps

0000 0101b : 128 kbps

0000 0110b : 160 kbps

0000 0111b : 192 kbps

0000 1000b : 224 kbps

15 0000 1001b : 256 kbps

0000 1010b : 320 kbps

0000 1011b : 384 kbps

0000 1100b : 448 kbps

0000 1101b : 768 kbps

20 0000 1110b : 1536 kbps

It is important that only the bit rate of a basic stream excluding an extended stream is recorded when the corresponding audio stream is the MPEG audio stream having the extended stream. The reason is that the extended stream cannot be expressed by the above-mentioned fixed bit rate because it carries out the compression using the variable length coding method.

25

**A\_ATR1 (Attribute of Audio Stream 1):**

The following audio attribute information corresponding to an audio stream 1 (corresponding to the above described audio stream #2 provided for after-recording) is recorded in accordance with a format shown in Fig. 13. Individual fields are the same as the above-mentioned A\_ATR0.

**SP\_ATR (Sub-picture Attribute):**

The following sub-picture attribute information is recorded in accordance with a format as shown in Fig. 14.

**Application Flag:**

Any one of the following values for identifying application information is recorded therein.

00b : No application

01b : Subtitles

10b : Animation

**SP\_PLT (Sub-picture Color Palette):**

Color palette information for a sub-picture is recorded in accordance with the format shown in Fig. 14.

**"M\_AVFI" (Fig. 15):**

M\_AVFI (Motion picture AV File Information) comprises information necessary for giving access to movie VOB (M\_VOB), M\_AVFI\_GI, M\_VOBI\_SRP and M\_VOBI.

**"M\_AVFI\_GI" (Fig. 15):**

M\_VOBI\_SRP\_Ns is recorded in M\_AVFI\_GI (Motion picture AV File Information General Information).

**M\_VOBI\_SRP\_Ns (Number of Movie VOB Information Search Pointer):**

Number of M\_VOBI\_SRP is recorded therein.

"M\_VOBI\_SRP" (Fig. 15):

M\_VOBI\_SRP (Movie VOB Information Search Pointer) stores address information for accessing each M\_VOBI.

5 M\_VOBI\_SA (Movie VOB Information Start Address):

The start address of M\_VOBI is recorded therein. The indicated address herein can be used in seeking operation for accessing the VOB information.

"M\_VOBI" (Fig. 16):

10 M\_VOBI (Movie VOB Information) comprises management information of movie VOB, M\_VOB\_GI, SMLI, AGAPI, TMAPI and CP\_MNGI.

"M\_VOB\_GI" (Fig. 16):

M\_VOB\_GI (Movie VOB General Information) stores the following information as the general information of the Movie VOB.

15 VOB\_TY (VOB Type):

The attribute information of VOB is recorded therein in accordance with a format shown in Fig. 17.

TE:

20 Any one of the following values for identifying the status of the VOB is recorded therein.

0b : Normal status

1b : Temporary erasing status

A0\_STATUS:

25 Any one of the following values for identifying the status of an audio stream 0 is recorded therein.

00b : Original status

01b : Rewritten status

#### A1\_STATUS:

5 Any one of the following values for identifying the status of an audio stream 1 is recorded therein.

00b : Original status

01b : Rewritten status

10b : Dummy status for after-recording

11b : After-recorded status

#### 10 APS:

Any one of the following values for identifying analog copy preventing signal control information is recorded therein.

00b : No APS

01b : Type 1

15 10b : Type 2

11b : Type 3

#### SML\_FLG:

Any one of the following values for identifying whether or not the VOB is seamlessly reproduced together with the VOB present just before.

20 0b : Seamless reproduction is impossible.

1b : Seamless reproduction is possible.

#### A0\_GAP\_LOC:

Recorded therein is any one of the following values indicative of the presence of an audio reproducing gap in the audio stream 0 and VOB  
25 having an audio reproducing gap interval multiplexed.

00b : No audio reproducing gap.

01b : Audio reproducing gaps are multiplexed to a head VOB.

10b : Audio reproducing gaps are multiplexed to a second VOB.

11b : Audio reproducing gaps are multiplexed to a third VOB.

## 5 A1\_GAP\_LOC:

Recorded therein is any one of the following values indicative of the presence of an audio reproducing gap in the audio stream 1 and VOB having an audio reproducing gap interval multiplexed.

00b : No audio reproducing gap

10 01b : Audio reproducing gaps are multiplexed to a head VOB.

10b : Audio reproducing gaps are multiplexed to a second VOB.

11b : Audio reproducing gaps are multiplexed to a third VOB.

VOB\_REC\_TM (VOB recording date and time):

15 The date and time on which the VOB was recorded is recorded therein in the same format as in the PL\_CREATE\_TM shown in Fig. 9. It is important that the recording date and time indicates the recording date and time of the display video frame of the VOB head and the VOB\_REC\_TM should also be corrected when the VOB head video frame is changed by edit or partial erasure. When the recording date and time is to be displayed synchronously  
20 with the reproduction of the VOB as often seen in a cam coder, the recording date and time is possible to obtain by adding an elapsed time in the VOB to the VOB\_REC\_TM.

VOB\_REC\_TM\_SUB (VOB Recording Date and Time Difference Information):

25 VOB\_REC\_TM\_SUB is a field for absorbing the error of the VOB\_REC\_TM to be modified when the VOB head video frame is changed by

the edit and the partial erasure on the VOB. The VOB\_REC\_TM has only information about year, month, day, hour, minute and second as shown in Fig. 9. Therefore, in the case where the edit or erasure is carried out in each frame or field, the VOB\_REC\_TM cannot provide a sufficient recording precision. By using this field, therefore, a fraction is recorded.

M\_VOB\_STIN (M\_VOB\_STI Number):

M\_VOB\_STI number corresponding to the VOB is recorded therein. M\_VOB#STI number shown herein is the recording order in the above-mentioned M\_VOB\_STI table.

10 VOB\_V\_S\_PTM (VOB Video Start PTM):

The display start time of the VOB is recorded therein with the same reference time as a time stamp in a stream.

VOB\_V\_E\_PTM (VOB Video End PTM):

15 The display end time of the VOB is recorded therein with the same reference time as a time stamp in a stream. It should be noted that the time stamp in the stream indicates the display start time of the frame, while VOB\_V\_E\_PTM stores the display end time, that is, a time obtained by adding the display period of the frame to the display start time.

"SMLI" (Fig. 16):

20 SMLI (Seamless Information) stores the following information necessary for seamless reproduction with the last VOB. Moreover, this field is provided only when "1b" is recorded in the above-mentioned SML\_FLG.

VOB\_FIRST\_SCR (VOB Head SCR):

SCR in the first pack of the VOB is recorded.

25 PREV\_VOB\_LAST\_SCR (Previous VOB Last SCR):

SCR of the last pack of the previous VOB is recorded therein.

"AGAPI" (Fig. 16):

AGAPI (Audio Gap Information) stores the following information necessary for processing an audio reproducing gap in a decoder. Moreover, this field is provided in the case where a value other than "00b" is recorded in either the above-mentioned A0\_GAP\_LOC or A1\_GAP\_LOC.

VOB\_A\_STP\_PTM (VOB Audio Stop PTM):

The time of the audio reproducing gap, that is, the time that the decoder temporarily stops audio reproduction is recorded therein with the same reference time as a time stamp in a stream.

VOB\_A\_GAP\_LEN (VOB Audio Gap Length):

The time length of an audio reproducing gap is recorded with a precision of 90 kHz.

"CP\_MNGI" (Fig. 16):

CP\_MNGI (Copy Management Information) comprises copy management information for the VOB, CPG\_STATUS and CPGI.

CPG\_STATUS (Copy Protecting Status):

As the copy protecting status of the VOB, values for identifying "copy free" or "one generation copying" are recorded therein.

CPGI (Copy Protecting Information):

Copy protecting information applied to the VOB is recorded therein.

"TMAPI" (Fig. 18):

TMPAI (Time Map Information) comprises TMAP\_GI, TM\_ENT and VOBU\_ENT.

"TMAP\_GI" (Fig. 18):

TMAP\_GI (TMAP General Information) comprises TM\_ENT\_Ns, VOBU\_ENT\_Ns, TM\_OFS and ADR\_OFS. Each field is as follows.

TM\_ENT\_Ns (Number of TM\_ENT):

5           Number of fields of TM\_ENT which will be described below is recorded therein.

VOBU\_ENT\_Ns (Number of VOBU\_ENT):

          Number of fields of VOBU\_ENT which will be described below is recorded therein.

10    TM\_OFS (Time Offset):

          The offset value of a time map is recorded therein with a video field precision.

ADR\_OFS (Address Offset):

15           An offset value in the AV file of the head of the VOB is recorded therein.

"TM\_ENT" (Fig. 18):

          TM\_ENT (Time Entry) comprises the following fields as access point information for each constant interval TMU. TMU for NTSC is 600 video fields (NTSC), while TMU for PAL is 500 video fields.

20    VOBU\_ENTN (VOBU\_ENT Number):

          The entry number of VOBU including a time indicated by the TM\_ENT ( $\text{TMU} \times (N-1) + \text{TM\_OFS}$  for Nth TM\_ENT) is recorded therein.

TM\_DIFF (Time Difference):

25           A difference between a time indicated by the TM\_ENT and the display start time of VOBU indicated by the above-mentioned VOBU\_ENTN is

recorded therein.

**VOBU\_ADR (VOBU Address):**

A head address in the VOB of the VOBU indicated by the above-mentioned VOBU\_ENTN is recorded therein.

5 **"VOBU\_ENT" (Fig. 19):**

VOBU\_ENT (VOBU Entry) stores the following structure information of the corresponding VOBU in a format shown in Fig. 19. By adding succeeding fields in order, it is possible to obtain a time and address information necessary for accessing desirable VOBU.

10 **ISTREF\_SZ:**

Number of packs from a VOBU head pack to a pack including last data of the head I picture in the VOBU is recorded therein.

**VOBU\_PB\_TM:**

The reproducing time length of the VOBU is recorded therein.

15 **VOBU\_SZ:**

The data amount of the VOBU is recorded therein.

**"S\_AVFIT" (Fig. 20):**

S\_AVFIT (Still picture AV File Information Table) has management information corresponding to the still picture AV file

20 "RTR\_STO.VRO" recorded therein, and comprises S\_AVFITI, S\_VOB\_STI and S\_AVFI.

**"S\_AVFITI" (Fig. 20):**

S\_AVFITI (Still Picture AV File Information Table Information) stores the following information necessary for accessing S\_VOB\_STI and

25 S\_AVFI.

S\_AVFI\_Ns (Number of Still Picture AV File Information):

"0" or "1" is recorded therein as the S\_AVFI number. This value also corresponds to the still picture AV file number, that is, the presence of the RTR\_STO.VRO file.

5 S\_VOB\_STI\_Ns (Number of Still Picture VOB Stream Information):

Number of S\_VOB\_STI which will be described below is recorded therein.

S\_AVFI\_EA (Still Picture AV File Information End Address):

The end address of S\_AVFI is recorded therein.

10 "S\_VOB\_STI" (Fig. 20):

In S\_VOB\_STI (Still Picture VOB Stream Information) is recorded the following information as the stream information of the still picture VOB.

V\_ATR (Video Attribute):

15 Video compression mode, TV system, Aspect ratio, and Video resolution are recorded therein as video attribute information. Individual fields are the same as V\_ATR in the above-mentioned M\_VOB\_STI.

OA\_ATR (Audio Stream Attribute):

20 Audio coding mode, Application Flag, Quantization/DRC, fs, and Number of Audio channels are recorded as audio stream attribute information. Individual fields are the same as A\_ATR0 in the above-mentioned M\_VOB\_STI.

SP\_ATR (Sub-picture Attribute):

Application Flag is recorded therein as sub-picture attribute information. The field is the same as SP\_ATR in the above-mentioned M\_VOB\_STI.

25 SP\_PLT (Sub-picture Color Palette):

Color palette information for a sub-picture is recorded therein. A recording format is the same as SP\_PLT in the above-mentioned M\_VOB\_STI.

"S\_AVFI" (Fig. 23):

5 S\_AVFI (Still Picture AV File Information) comprises information necessary for accessing a still picture VOB, S\_AVFI\_GI, S\_VOGL\_SRP and S\_VOGL.

"S\_AVFI\_GI" (Fig. 23):

S\_AVFI\_GI (Still Picture AV File information General Information) stores S\_VOGL\_SRP\_Ns.

10 S\_VOGL\_SRP\_Ns (Number of Still Picture VOB Group Search Pointer):

Number of fields of S\_VOGL\_SRP which will be described below is recorded therein.

"S\_VOGL\_SRP" (Fig. 23):

15 S\_VOGL\_SRP (Static VOB Group Information Search Pointer) stores S\_VOGL\_SA.

The start address of S\_VOGL is recorded in the S\_VOGL\_SA (Still Picture VOB Group Information Start Address).

"S\_VOGL" (Fig. 23):

20 The S\_VOGL (Still Picture VOB Group Information) comprises the management information of the still picture VOB, S\_VOGL\_GI, S\_VOB\_ENT and CP\_MNGI.

"S\_VOG\_GI" (Fig. 23):

25 The following information is recorded as the general information of a still picture VOB group in S\_VOG\_GI (Still Picture VOB Group General Information).

**S\_VOB\_Ns (Number of Still Picture VOBs):**

Number of still picture VOBs in the still picture VOB group is recorded therein.

**S\_VOB\_STIN (S\_VOB\_STI Number):**

5 Recorded therein is S\_VOB\_STI number of S\_VOB\_STI which stores the stream information of the still picture VOB. The S\_VOB\_STI number is the recording order in the above-mentioned S\_VOB\_STI table.

**FIRST\_VOB\_REC\_TM (First VOB Recording Data and Time):**

10 The recording date and time information of the first (head) still picture VOB in the still picture VOB group is recorded therein.

**LAST\_VOB\_REC\_TM (Last VOB Recording Data and Time):**

The recording date and time information of the last still picture VOB in the still picture VOB group is recorded therein.

**S\_VOB\_SA (Still Picture VOB Group Start Address):**

15 The start address of the still picture VOB group in the RTR\_STO.VRO file is recorded therein.

**"CP\_MNGI":**

20 CP\_MNGI (Copy Management Information) stores copy management information related to the still picture VOB group. Individual fields are the same as the CP\_MNGI of the above-mentioned M\_VOBI.

**"S\_VOB\_ENT" (Fig. 24):**

S\_VOB\_ENT (Still Picture VOB Entry) corresponds to individual still picture VOBs in the still picture VOB group, and is divided into the following types A and B depending on the presence of audio data.

25 **"S\_VOB\_ENT (Type A)" (Fig. 24):**

The type A comprises S\_VOB\_ENT\_TY and V\_PART\_SZ.  
Individual fields are as follows.

S\_VOB\_ENT\_TY (Still Picture VOB Entry Type):

5 The type information of the still picture VOB is recorded therein in  
a format shown in Fig. 25.

MAP\_TY:

Any one of the following values for identifying the type A or the  
type B is recorded therein.

00b : Type A

10 01b : Type B

TE:

Any one of the following values for identifying the status of the still  
picture VOB is recorded therein.

0b : Normal status

15 1b : Temporary erasing status

SPST\_Ns:

Number of sub-picture streams in the still picture VOB is recorded  
therein.

V\_PART\_SZ (Video Part Size):

20 The data amount of the still picture VOB is recorded therein.

"S\_VOB\_ENT (Type B)" (Fig. 24):

The type B has A\_PART\_SZ and A\_PB\_TM in addition to  
S\_VOB\_ENT\_TY and V\_PART\_SZ. Individual fields are as follows.

S\_VOB\_ENT\_TY (Still Picture VOB Entry Type):

25 The type information of the still picture VOB is recorded therein.

Individual fields are the same as the above-mentioned type A.

**V\_PART\_SZ (Video Part Size):**

The data amount of a video part in the still picture VOB is recorded therein.

5 **A\_PART\_SZ (Audio Part Size):**

The data amount of an audio part in the still picture VOB is recorded therein.

**A\_PB\_TM (Audio Reproducing Time):**

10 The reproducing time length of the audio part of the still picture VOB is recorded.

"UD\_PGCIT" (Fig. 26):

UD\_PGCIT (User-Defined PGC Information Table) comprises UD\_PGCITI, UD\_PGCI\_SRP and UD\_PGCI.

"UD\_PGCITI" (Fig. 26):

15 UD\_PGCITI (User-Defined PGC Information Table Information) stores the following information constituting the user-defined PGC information table.

UD\_PGCI\_SRP\_Ns (Number of User-Defined PGC Information Search Pointers):

20 Number of UD\_PGCI\_SRP is recorded therein.

UD\_PGCIT\_EA (User-Defined PGC Information Table End Address):

The end address of UD\_PGCIT is recorded therein.

"UD\_PGCI\_SRP" (Fig. 26):

25 UD\_PGCI\_SA is recorded in UD\_PGCI\_SRP (User-Defined PGC Information Search Pointer).

UD\_PGCI\_SA (User-Defined PCG Information Start Address):

The start address of UD\_PGCI is recorded in UD\_PGCI\_SA. A seek is carried out up to a recorded address when the PGCI is accessed.

"UD\_PGCI" (Fig. 26):

5 The details of the UD\_PGCI (User-Defined PGC Information) will be described in the following PGCI.

"O\_PGCI" (Fig. 5):

The details of O\_PGCI (Original PGC Information) will be described in the following PGCI.

10 "TXTDT\_MG" (Fig. 27):

TXTDT\_MG (Text Data Management) comprises TXTDTI, IT\_TXT\_SRP and IT\_TXT. Individual fields are as follows.

"TXTDTI" (Fig. 27):

15 TXTDTI (Text Data Information) comprises CHRS, IT\_TXT\_SRP\_Ns and TXTDT\_MG\_EA.

CHRS (Character Set Code):

A character set code to be used for the IT\_TXT is recorded therein.

IT\_TXT\_SRP\_Ns (Number of IT\_TXT Search Pointers):

Number of the IT\_TXT\_SRP is recorded therein.

20 TXTDT\_MG\_EA (Text Data Management End Address):

The end address of the TXTDT\_MG is recorded therein.

"IT\_TXT\_SRP" (Fig. 27):

IT\_TXT\_SRP (IT\_TXT Search Pointer) stores the following as access information to corresponding IT\_TXT.

25 IT\_TXT\_SA (IT\_TXT Start Address):

The start address of the IT\_TXT is recorded therein. When the IT\_TXT is accessed, a seek is carried out up to this address.

IT\_TXT\_SZ (IT\_TXT Size):

5 The data size of the IT\_TXT is recorded therein. When the IT\_TXT is to be read, data with only this size is read.

"IT\_TXT" (Fig. 27):

10 The IT\_TXT comprises a plurality of sets or one set, each set having IDCD (identification code), TXT (text) corresponding to the IDCD and TMCD (termination code). When there is no TXT corresponding to the IDCD, the IDCD and the TMCD may make a set without TXT. The IDCD is defined as follows.

Genre code:

	30h : Movie
	31h : Music
15	32h : Drama
	33h : Animation
	34h : Sports
	35h : Documentary
	36h : News
20	37h : Weather
	38h : Education
	39h : Hobby
	3Ah : Entertainment
	3Bh : Art (play, opera)
25	3Ch : Shopping

**Input Source Code:**

60h : Broadcasting station

61h : Cam coder

62h : Photograph

5 63h : Memo

64h : Others

**"PGCI" (Fig. 28):**

PGCI (PGC Information) has a data structure which is common to O\_PGCI and UD\_PGCI, and comprises PGC\_GI, PGI, CI\_SRP and CI.

10 **"PGC\_GI" (Fig. 28):**

PGC\_GI (PGC General Information) comprises PG\_Ns and CI\_SRP\_Ns as the PGC general information. Individual fields are as follows.

**PG\_Ns (Number of Programs):**

15 Number of programs in the PGC is recorded therein. For the user-defined PGC, "0" is recorded in this field because the user-defined PGC has no program.

**CI\_SRP\_Ns (Number of CI\_SRP):**

Number of CI\_SRP which will be described below is recorded.

**"PGI" (Fig. 28):**

20 PGI (Program Information) comprises PG\_TY, C\_Ns, PRM\_TXTI, IT\_TXT\_SRPN and THM\_PTRI. Individual fields are as follows.

**PG\_TY (Program Type):**

The following information indicative of the status of this program is recorded therein by using a format shown in Fig. 29.

25 **Protect (protect):**

0b : Normal status

1b : Protect status

C\_Ns (Number of Cells):

Number of cells in this program is described.

5 PRM\_TXTI (Primary Text Information):

Text information indicative of the contents of this program is recorded therein. The details are the same as in the above-mentioned PL\_SRPT.

IT\_TXT\_SRPN (IT\_TXT\_SRP Number):

10 In the case where information indicative of the contents of this program is optionally recorded as the IT\_TXT in addition to the above-mentioned primary text, the number of IT\_TXT\_SRP recorded in the TXTDT\_MG is recorded in this field.

THM\_PTRI (Thumb Nail Pointer Information):

15 Thumb nail information which is representative of this program is described therein. The details of THM\_PTRI are the same as in the THM\_PTRI of the above-mentioned PL\_SRPT.

"CI\_SRP" (Fig. 28):

20 CI\_SRP (Cell Information Search Pointer) stores address information for accessing the cell information.

CI\_SA (Cell Information Start Address):

The start address of the cell information is recorded therein. In the case where the cell is accessed, a seek is carried out up to this address.

"CI" (Fig. 30):

25 CI (Cell Information) is classified into MI\_CI for a motion picture

and S\_CI for a still picture.

"M\_CI" (Fig. 30):

M\_CI (Motion picture Cell Information) comprises M\_C\_GI and M\_C\_EPI.

5 "M\_C\_GI" (Fig. 30):

M\_C\_GI (Motion picture Cell General Information) has the following basic information constituting a cell.

C\_TY (Cell Type):

10 The following information for identifying a motion picture cell and a still picture cell are recorded in a format shown in Fig. 31.

C\_TY1:

000b : Motion Picture (Movie) Cell

001b : Still Picture Cell

M\_VOBI\_SRPN (Movie VOB Information Search Pointer Number):

15 The search pointer number of movie VOB information to which this cell corresponds is recorded therein. In the case where access is to be given to stream data to which this cell corresponds, access is first given to a movie VOB information search pointer number indicated by this field.

C\_EPI\_Ns (Number of Cell Entry Point Information):

20 Number of entry point present in this cell is recorded therein.

C\_V\_S\_PTM (Cell Video Start Time):

The reproducing start time of this cell is recorded in a format shown in Fig. 10.

C\_V\_E\_PTM (Cell Video End Time):

25 The reproducing end time of this cell is recorded in the format

shown in Fig. 10. The effective interval of this cell in the VOB to which this cell corresponds is specified by using the C\_V\_S\_PTM and C\_V\_E\_PTM.

"M\_C\_EPI" (Fig. 32):

5 M\_C\_EPI (Motion Picture Cell Entry Point Information) is classified into a type A and a type B depending on the presence of a primary text.

"M\_C\_EPI (Type A)" (Fig. 32):

M\_C\_EPI (Type A) comprises the following information indicative of an entry point.

10 EP\_TY (Entry Point Type):

The following information for identifying the type of this entry point is recorded in accordance with a format shown in Fig. 33.

EP\_TY1:

00b : Type A

15 01b : Type B

EP\_PTM (Entry Point Time):

A time that the entry point is put is recorded in accordance with the format shown in Fig. 10.

"M\_C\_EPI (Type B)" (Fig. 32):

20 M\_C\_EPI (Type B) has the following PRM\_TXTI in addition to the EP\_TY and EP\_PTM included in the type A.

PRM\_TXTI (Primary Text Information):

Recorded therein is text information indicative of the contents of locations indicated by this entry point. The details are the same as in the  
25 above-mentioned PL\_SRPT.

"S\_CI" (Fig. 30):

S\_CI (Still Picture Cell Information) comprises S\_C\_GI and S\_C\_EPI.

"S\_C\_GI" (Fig. 30):

5 S\_C\_GI (Still Picture Cell General Information) has the following basic information constituting a cell.

C\_TY (Cell type):

Information for identifying a motion picture cell and a still picture cell are recorded. The details are the same as in the above-mentioned motion  
10 picture cell.

S\_VOI\_SRPN (Still Picture VOB Group Information Search Pointer Number):

Recorded therein is the search pointer number of still picture VOB group information to which this cell corresponds. In the case where access is to be given to stream data to which this cell corresponds, access is first given to a  
15 still picture VOB group information search pointer number indicated by this field.

C\_EPI\_Ns (Number of Cell Entry Point Information):

Number of entry points present in this cell is recorded.

S\_S\_VOB\_ENTN (Start Still Picture VOB Number):

The reproducing start still picture VOB number of this cell is  
20 recorded in the format shown in Fig. 11. The still picture VOB number is the order in the S\_VOG indicated by the above-mentioned S\_VOI\_SRPN.

E\_S\_VOB\_ENTN (End Still Picture VOB Number):

The reproducing end still picture VOB number of this cell is recorded in the format shown in Fig. 11. The still picture VOB number is the  
25 order in the S\_VOG indicated by the above-mentioned S\_VOI\_SRPN. The

effective interval of this cell in the S\_VOG to which the cell corresponds is specified by using the S\_S\_VOB\_ENTN and E\_S\_VOB\_ENTN.

"S\_C\_EPI" (Fig. 32):

5 S\_C\_EPI (Still Picture Cell Entry Point Information) is classified into a type A and a type B depending on the presence of a primary text.

"S\_C\_EPI (Type A)" (Fig. 32):

S\_C\_EPI (Type A) comprises the following information indicative of an entry point.

EP\_TY (Entry Point Type):

10 The following information for identifying the type of this entry point is recorded in accordance with a format shown in Fig. 33.

EP\_TY1:

00b : Type A

01b : Type B

15 S\_VOB\_ENTN (Still Picture VOB Entry Number):

A number of still picture on which an entry point is put is recorded therein in accordance with the format shown in Fig. 11.

"S\_C\_EPI (Type B)" (Fig. 32):

20 S\_C\_EPI (Type B) has the following PRM\_TXTI in addition to the EP\_TY and S\_VOB\_ENTN included in S\_C\_EPI of type A.

PRM\_TXTI (Primary Text Information):

Recorded therein is text information indicative of the contents of locations indicated by this entry point. The details are the same as in the above-mentioned PL\_SRPT.

(DVD Recorder)

Next, the structure of the DVD recorder in this embodiment will be described.

DVD-recorder of this embodiment has almost same structure as one of the first embodiment but differs in the following point. That is, in the DVD-recorder, the system controller 7802 includes an after-recording check section 78021 and an after-recording operation section 78022 for performing after-recording as shown in Fig.53.

Though the operation of the recorder of this embodiment is almost same as in the first embodiment, great different point is that the after-recording check section 78021 in the recorder of this embodiment checks in advance whether the recorder has an ability to perform after-recording for audio stream which is intended to be after-recorded.

As described above, the optical disc of this embodiment has bit rate information ("Bitrate") as attribute information of a dummy audio stream provided for after-recording in addition to audio coding mode information, information of number of audio channels.

With reference to the audio attribute information, the DVD recorder checks in advance whether or not the recorder can perform after-recording operation by using the dummy audio stream.

Concretely, it is determined whether after-recording operation is possible or not by comparing audio coding mode, audio channel number and bit rate with encode ability of the DVD recorder.

When the after-recording operation is determined to be possible, the after-recording operation is performed as in the first embodiment. When the

after-recording operation is determined to be impossible, user is notified that the after-recording operation is impossible via the user interface 7801 in a predetermined manner (for example, to display message). This operation is described below with reference to flow charts in Figs. 54, 55 and 56.

5 Referring to Fig. 54, on receiving user request for after-recording to a desired program (PG) via the user interface 7801 (S1), the system controller 7802 reads in movie VOB information (M\_VOBI) and movie VOB stream information (M\_VOB\_STI) related to the designated program (PG) (S2). Then, possibility of after-recording operation in the recorder is checked (S3).  
 10 That is, it is determined whether or not the after-recording operation is possible with reference to M\_VOBI and M\_VOB\_STI (S3). With the result, when the after-recording operation is determined to be possible (S4), the controller starts the after-recording operation (S5). When the after-recording operation is determined to be impossible (S4), the controller notifies the user that the after-  
 15 recording operation is impossible (for example, displays message) (S6).

The check routine of possibility of after-recording operation (step S3) is performed as follows in accordance with the flowchart of Fig. 55.

The controller checks number of audio streams based on AST\_Ns of M\_VOB\_STI (in Fig. 12) (S31). When there are two audio streams (S32),  
 20 attribute of each audio stream is checked or determine whether or not each audio stream is in a state where it is possible to perform after-recording operation to the stream (referred to as "after-recordable state") (S33). Details of this process will be described later. With the result of the check, when audio stream is in after-recordable state (S34), coding mode ("Audio Coding Mode")  
 25 (see Fig. 13) in A\_ATR1 of M\_VOB\_STI is checked (S35). When an encoder of

the DVD recorder is operable in the checked coding mode (S36), bit rate ("Bitrate") in A\_ATR1 of M\_VOB\_STI is checked (S37). When the encoder is operable in the checked bit rate (S38), it is decided that the after-recording operation is "possible" (S39). Otherwise, it is decided that after-recording operation is "impossible" (S40).

The check routine of attribute of audio stream (step S33) is performed as follows in accordance with the flowchart in Fig. 56.

Firstly, it is determined whether the A1\_STATUS of audio stream for after-recording (audio stream 2) (see Fig. 17) is in "dummy state for after-recording" (S321). When the A1\_STATUS is in "dummy state for after-recording", the audio stream is decided to be in "after-recordable state" (S322). It is noted that "dummy state for after-recording" indicates that the audio stream is prepared for after-recording but that after-recording data have not been recorded yet in the audio stream. When the A1\_STATUS is not in "dummy state for after-recording", notice is served to user that the audio stream has already been after-recorded, and user's response is waited (S323). When after-recording is ordered by user in the response (S324), the audio stream is decided to be in after-recordable state (S322). When after-recording is not ordered by user in the response (S324), the audio stream is decided not to be in after-recordable state (S325).

The DVD recorder according to this embodiment creates the management information for each motion picture recording. The DVD recorder especially creates audio coding mode, number of audio channels and bit rate information as an audio stream attribute information, and records them onto the optical disc.

While in this embodiment the recorder is provided for DVD-RAM disc, this invention is not limited to DVD-RAM but applicable to re-writable disc.

While in this embodiment details of data structure on the disc is described, the data structure is not limited to the structure described above.

5 That is, this invention can be implemented by the recorder that compares audio attribute information including bit rate with encoding ability in advance when the recorder performs after-recording.

While in this embodiment the description is made for two audio streams, same advantage could be obtained when only one audio stream is recorded as in the case where two audio streams are recorded.

10 Although the present invention has been described in connection with specified embodiments thereof, many other modifications, corrections and applications are apparent to those skilled in the art. Therefore, the present invention is not limited by the disclosure provided herein but limited only to the scope of the appended claims.
